

EXHIBIT P1-N

Supplemental End-to-End Demonstration Package

Source-to-Output Workflow for ERP-Native Digital-Asset Accounting and Reporting Readiness

2. Purpose and Scope

Exhibit P1-N is submitted as a supplemental end-to-end demonstration package prepared in response to the RFE. It does not merely resubmit previously provided project evidence. Instead, it organizes relevant implementation artifacts into a source-to-output workflow showing how the proposed framework is designed to convert digital-asset transaction data into ERP-native accounting records, audit trails, Form 1099-DA field mapping, Form 8949 reconciliation, and CPA-reviewable evidence. Some underlying implementation artifacts may overlap with materials previously submitted, but this exhibit presents them in a new explanatory format responsive to the RFE's concerns regarding practical applicability, broader use, and prospective impact.

This exhibit is limited in scope. It demonstrates practical applicability and provides a reviewable pathway from source data to professionally reviewable output. It does not restate the national-importance argument set out in the Prong 1 response, and it does not duplicate the petition cover letter, USCIS forms, fee materials, credentials, or general recommendation letters.

3. What This Exhibit Does and Does Not Claim

To assist the adjudicator and to avoid any overstatement, the following limitations apply throughout this exhibit. This exhibit:

Does not claim integration with the Internal Revenue Service (IRS), and does not claim that the framework files, submits, or transmits any tax form to any tax authority.

Does not claim automatic filing of any return or report.

Does not provide tax, legal, audit, or accounting advice.

Does not replace certified public accountants (CPAs), auditors, tax preparers, or professional judgment; its outputs are designed to be suitable for professional review.

Does not claim government endorsement, certification, or guaranteed adoption.

Does not claim production deployment in the United States unless separately documented elsewhere in the record.

Consistent with the underlying implementation artifacts, the demonstrated workflow operates on a non-custodial, read-only basis with respect to payment data. It does not execute payments, hold customer funds, or function as a payment processor, payment facilitator, or money transmitter of any kind; its function is limited to reading completed transaction data and recording that data within an internal accounting system.

4. End-to-End Workflow Overview

The proposed framework is designed to support the following source-to-output sequence. Each stage corresponds to a workflow step demonstrated in the sections that follow.

5. Demonstration Artifact Table

The table below maps each workflow step to the implementation artifact that demonstrates it, what the artifact shows, the relevant output, and the limitation that prevents overstatement; "Original Exhibit 5: Case Study 5" refers to previously submitted project evidence that remains part of the record and is cross-referenced here. This exhibit does not resubmit the original exhibit; it organizes selected implementation artifacts and newly generated outputs into a source-to-output workflow responsive to the RFE.

6. Workflow Step 1 — Transaction Ingestion

The framework is designed to ingest completed digital-asset payment events from an external provider into an ERP-native workflow. As shown in the implementation artifacts, an integration (middleware) layer queries the external payment provider's API at regular intervals to retrieve completed payment events and delivers them into the ERP. The architecture deliberately

separates payment execution, which remains entirely with the external provider, from accounting, which remains within the ERP system of record.

The supporting project evidence also demonstrates broad payment-channel ingestion experience, including integration with multiple payment processors and gateways, which establishes the practical capability underlying this step.

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Figure 1 — System Architecture Overview,” external payment provider API → middleware integration layer → ERP system of record, labeled “Data Transformation Only — No Custody of Funds.”]

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Figure 2 — Data Flow Sequence” and the “Payment Provider Configuration in Odoo ERP” / API integration configuration screenshot.]

[I-140 - EXHIBIT 5 - CASE STUDY 5: integration-expertise list of supported payment processors and gateways.]

Caption: This artifact demonstrates the framework's intended ability to ingest or map external transaction records into an ERP-native workflow. It does not claim direct IRS integration or certified reporting.

7. Workflow Step 2 — Normalized Ledger / Transaction Classification

After ingestion, imported transaction data is normalized from the provider API's native format into a standardized structure that is compatible with the ERP data model. The framework applies repeatable business logic to map each transaction to the appropriate accounting dimensions, revenue categories, and customer records within the ERP chart of accounts.

The emphasis at this step is repeatable classification logic and reviewability: the same standardized transformation is applied to every transaction, so that the resulting internal records are consistent and can be independently inspected, rather than reflecting ad hoc, per-client handling.

[I-140 - EXHIBIT 5 - CASE STUDY 5: narrative describing normalization of native API data into an ERP-compatible structure and mapping to accounting dimensions.]

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Crypto Payment” configuration screen in the ERP accounting module.]

Caption: This artifact demonstrates repeatable, reviewable classification of ingested transactions into structured internal records. It does not claim a certified or client-specific result.

8. Workflow Step 3 — Fair-Value Measurement Support

The framework is designed to support fair-value measurement by capturing the applicable valuation at the time of transaction using contemporaneous market data, and by recording the valuation timestamp and pricing source alongside each transaction. This is the accounting standard the workflow is designed to support — FASB ASU 2023-08, which addresses fair-value measurement and periodic remeasurement of certain crypto assets — and the design contemplates period-end remeasurement of recorded positions.

Identifying FASB ASU 2023-08 here describes the standard the workflow is designed to support. It is not offered as proof of compliance with that standard, which remains a determination for the relevant accounting professionals.

[I-140 - EXHIBIT 5 - CASE STUDY 5: narrative stating that exchange-rate / valuation is captured at the time of transaction using contemporaneous market data.]

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Figure 3 — Accounting Entry Automation Workflow,” showing an “Exchange Rate Lookup” step sourced from market data.]

Caption: This artifact demonstrates that the workflow is designed to capture valuation timestamp and pricing source in support of fair-value measurement. It does not claim compliance with FASB ASU 2023-08 or provide accounting advice.

9. Workflow Step 4 — ERP Journal Entry Generation

For each ingested transaction, the framework is designed to generate the corresponding debit and credit entries and post them to the general ledger, reflecting receipt of revenue and the corresponding asset recognition. The implementation artifacts show automated journal-entry generation as part of an end-to-end accounting sequence (record the transaction with complete details → generate the appropriate debit/credit entry → reconcile to the related invoice → update the ledger and reports).

The screenshots provided are implementation artifacts showing relevant ERP journal-entry capability. They are not offered as proof of any completed U.S. deployment.

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Payment Transaction Entry in Odoo ERP” journal-entry screenshot (entry reference PBNK1/2026/00005) showing debit/credit lines.]

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Automated Journal Entry Example” showing a debit/credit posting.]

[I-140 - EXHIBIT 5 - CASE STUDY 5: numbered automated-accounting sequence — record transaction, generate DR/CR journal entry, reconcile, update ledger.]

Caption: These artifacts are implementation evidence showing relevant ERP journal-entry capability; they are not proof of completed U.S. deployment.

10. Workflow Step 5 — Audit Trail / Source Traceability

Each ERP record generated by the workflow is designed to include structured metadata linking the accounting entry back to its originating payment event, creating an auditable trail from the external payment notification through final posting in the general ledger. The integration layer is designed to log each API query, transformation operation, and record-creation event, providing an operational history that supports later review and troubleshooting.

Access to configuration is designed to be restricted through role-based access control, and the integration is designed to operate on a read-only basis without storing private keys — measures that support the integrity of the audit trail.

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Figure 4 — Transaction Traceability Model,” linking external payment ID → middleware record → journal entry → audit trail.]

[I-140 - EXHIBIT 5 - CASE STUDY 5: configuration setting indicating audit-trail logging is enabled.]

[I-140 - EXHIBIT 5 - CASE STUDY 5: “Figure 5 — Security Architecture” and the audit-logging narrative.]

Caption: This artifact demonstrates source traceability and operational logging designed to support reviewability. It does not provide assurance, audit, or advisory services.

11. Workflow Step 6 — Form 1099-DA Field Mapping

The workflow is designed to map captured transaction fields to the data elements relevant to Form 1099-DA reporting readiness. The sample mapping below is illustrative of how source fields are aligned to reporting-readiness fields. This is reporting-readiness field mapping only; the framework does not file, submit, or transmit any form to the IRS or any tax authority.

Caption: This artifact demonstrates a reporting-readiness mapping of captured fields to Form 1099-DA data elements. It does not file with the IRS and does not provide tax advice.

12. Workflow Step 7 — Form 8949 Reconciliation

The workflow is designed to produce a reconciliation suitable for tax-preparer review, aligning acquisitions and dispositions with proceeds, cost basis, resulting gain or loss, and a source transaction reference. The sample reconciliation below uses illustrative placeholder values to show the column structure; it is not actual transaction data and is not tax advice.

The screenshot below shows an Odoo-generated Form 8949 support output prepared for tax-preparer review. It is not an official IRS filing and does not constitute tax advice.

Supporting reconciliation capability is shown in the broader project evidence, which demonstrates automated bank-reconciliation and payment-to-invoice matching within the ERP.

[I-140 - EXHIBIT 5 - CASE STUDY 5: automated bank-reconciliation and payment-to-invoice matching narrative.]

Caption: This artifact demonstrates a reconciliation output structured for tax-preparer review. It is suitable for professional review and does not constitute tax advice.

13. Workflow Step 8 — CPA-Reviewable Evidence Package

The final output of the workflow is designed to be an organized evidence package suitable for professional review. A complete package is designed to assemble the following components:

Source transaction data (the captured digital-asset payment events).

Valuation support (fair-value record with valuation timestamp and pricing source).

Journal entries (the generated debit/credit postings to the general ledger).

Reconciliation output (the Form 8949-style reconciliation worksheet).

Audit log (the operational history linking entries to originating events).

Reviewer notes and limitations (a cover page stating scope and the non-claims above).

[I-140 - EXHIBIT 5 - CASE STUDY 5: comprehensive audit logging and the live multi-currency dashboard / financial outputs.]

Caption: This artifact demonstrates that the workflow's outputs can be assembled into a single, organized package suitable for professional review. It does not replace the CPA, auditor, or tax preparer who performs that review.

14. Mapping to RFE Concerns

The table below maps the RFE's concerns to the manner in which this exhibit responds and to the demonstration artifact relied upon. This mapping is limited to practical applicability and prospective impact; the national-importance argument is addressed in the Prong 1 response.

15. Conclusion

This exhibit does not prove adoption or certification. It demonstrates that the proposed framework has been reduced to an organized, reviewable, source-to-output workflow and that its outputs are designed for evaluation by CPAs, tax preparers, ERP implementers, and other relevant professionals.

Read together with the Business Plan (Exhibit P1-I), Technical Architecture (Exhibit P1-J), Public Repository / Reference Implementation (Exhibit P1-K), and practitioner letters (Exhibit P1-L), this demonstration package shows that the proposed endeavor has a concrete, reviewable implementation pathway rather than remaining a speculative concept.

Workflow Step	Artifact / Screenshot to Use	What It Demonstrates	Relevant Output	Limitation / No Overclaim
1. Transaction Ingestion	Original Exhibit 5: Case Study 5 195–196 (Figure 1 Architecture; Figure 2 Data Flow); API/payment-provider configuration screen	Polling/retrieval of completed payment events from an external provider API into an ERP workflow	Captured source transaction records	Read-only; no IRS integration; no custody of funds
2. Normalized Ledger / Classification	Original Exhibit 5: Case Study 5 195 (normalization narrative); p. 197 (crypto-payment configuration)	Mapping of native API data into a standardized ERP-compatible structure and accounting dimensions	Structured internal transaction records	Repeatable logic; reviewable; not client-specific customization
3. Fair-Value Measurement Support	Original Exhibit 5: Case Study 5 197–198 (Figure 3; valuation narrative); Odoo-generated fair-value / transaction valuation support screen	Valuation captured at transaction time using contemporaneous market data; pricing source recorded	Fair-value record with timestamp and source	Designed to support FASB ASU 2023-08; not proof of compliance
4. ERP Journal Entry Generation	Original Exhibit 5: Case Study 5 199–200 (journal entry screen); p. 134–135 (automated DR/CR example)	Generation of debit/credit entries posted to the general ledger from each event	Posted ERP journal entries	Implementation artifact; not proof of U.S. deployment
5. Audit Trail / Source Traceability	Original Exhibit 5: Case Study 5 199 (Figure 4 Traceability); p. 197 (audit-trail setting); p. 201 (Figure 5; logging)	Structured metadata linking each entry to its originating event; comprehensive logging	End-to-end audit trail	Operational logging only; no advisory or assurance function

Workflow Step	Artifact / Screenshot to Use	What It Demonstrates	Relevant Output	Limitation / No Overclaim
6. Form 1099-DA Field Mapping	Sample mapping table (Section 11); Odoo-generated 1099-DA readiness output	Mapping of captured fields to 1099-DA reporting-readiness fields	Reporting-readiness field map	Reporting-readiness only; framework does not file with the IRS
7. Form 8949 Reconciliation	Sample reconciliation table (Section 12); Original Exhibit 5: Case Study 5 136 (reconciliation automation); Odoo-generated Form 8949 support output	Reconciliation of acquisitions/dispositions with gain/loss and source references	Reconciliation worksheet output	Suitable for tax-preparer review; not tax advice
8. CPA-Reviewable Evidence Package	Original Exhibit 5: Case Study 5 201–203 (audit logs; live dashboard/financial outputs); Odoo-generated CPA / Accountant Review Package	Assembly of source data, valuation support, entries, reconciliation, and logs into one package	Reviewable evidence package	Designed for professional review; does not replace the reviewer

1099-DA Field (Reporting-Readiness)	Source Data Element in the Workflow	Notes
Transaction date	Timestamp of payment receipt captured at ingestion	Used for period and valuation alignment
Digital asset identifier	Asset code / identifier from the normalized record	Classified during normalization
Proceeds	Transaction value recorded at fair value	Valuation captured at transaction time
Quantity	Units of the digital asset in the transaction	From the normalized transaction record
Cost basis (where applicable)	Acquisition value where available in the record	Populated only where source data exists
Transaction ID / source reference	Unique external transaction identifier	Supports audit trail and traceability

Asset	Acquisition date	Disposition date	Proceeds	Cost basis	Gain / Loss	Source transaction reference
[ASSET]	[YYYY-MM-DD]	[YYYY-MM-DD]	[\$ amount]	[\$ amount]	[\$ amount]	[external txn ID]
[ASSET]	[YYYY-MM-DD]	[YYYY-MM-DD]	[\$ amount]	[\$ amount]	[\$ amount]	[external txn ID]

RFE Concern	How P1-N Responds	Demonstration Artifact
Specialized / customized tool	P1-N presents a standards-based, repeatable source-to-output workflow with an ERP-agnostic middleware design, rather than a single-client customization. The same transformation logic applies to every transaction.	Original Exhibit 5: Case Study 5 (Figures 1–3); (Framework Validation)
Open-source adoption is speculative	P1-N reduces the framework to organized, reviewable artifacts and outputs that are designed for evaluation by independent CPAs, tax preparers, and ERP implementers, and points to a public technical footprint.	Original Exhibit 5: Case Study 5 (public repository / module footprint); public repository / module-generated demonstration outputs
Lack of concrete prospective impact	P1-N demonstrates a working, reviewable end-to-end pathway from source data to a CPA-reviewable evidence package, supporting credible prospective impact through concrete, inspectable outputs.	Original Exhibit 5: Case Study 5 (Figures 2–6 and screenshots)
Compliance as an ordinary business requirement	P1-N shows the workflow is designed to support a specific accounting standard (FASB ASU 2023-08) through reusable infrastructure, with outputs suitable for professional review — demonstrating practical applicability rather than restating importance.	Original Exhibit 5: Case Study 5 (valuation at transaction time; Figure 3)
Localized business activity	P1-N presents a reusable, ERP-agnostic, standards-based workflow that is not tied to one client or location, designed to be readily applied by a range of adopters.	Original Exhibit 5: Case Study 5 (Framework Validation through case study)
